

SurveyBasket App Summary

Evidence source: SurveyBasket.Api repo contents

What It Is

SurveyBasket is an ASP.NET Core Web API for creating polls, managing questions, collecting votes, and returning results data. The repo shows JWT-based authentication, SQL Server persistence via EF Core, and OpenAPI/Swagger support in development.

Who It's For

Primary persona: Not found in repo.

Based on controllers and services, the API appears intended for an authenticated client app used by poll managers and poll participants.

What It Does

- Auth endpoints issue JWTs, refresh tokens, and support refresh-token revocation.
- Poll endpoints create, read, update, delete, list current polls, and toggle publish status.
- Question endpoints manage poll-scoped questions and toggle question active status.
- Voting endpoints return available questions for a user and accept submitted answers.
- Results endpoints return raw vote data, votes per day, and votes per question.
- FluentValidation validators and a global exception handler shape request validation and errors.
- Development mode exposes OpenAPI plus Swagger UI for exploring the API.

How It Works

- Host: Program.cs builds the ASP.NET Core app, enables CORS, controllers, HTTPS, authz, and dev OpenAPI/Swagger.
- API layer: Controllers include Auth, Polls, Questions, Votes, and Results.
- Business layer: Scoped services such as AuthService, PollService, QuestionService, VoteService, and ResultService handle use cases.
- Data layer: ApplicationDbContext uses EF Core with SQL Server and IdentityDbContext<ApplicationUser>.
- Security flow: AuthService uses UserManager<ApplicationUser> and JwtProvider to validate users, mint JWTs, and store refresh tokens.
- Mapping/validation: Mapster maps entities/contracts; FluentValidation auto-validates request models.
- Data flow: HTTP request -> controller -> service -> EF Core/Identity -> SQL Server -> mapped response or ProblemDetails error.

How To Run

1. Use a .NET SDK that supports target framework net10.0. Exact SDK version: Not found in repo.
2. Ensure SQL Server is available and update DefaultConnection in SurveyBasket.Api/appsettings.json if needed.
3. Set Jwt:Key before startup; the checked-in appsettings.json leaves it empty.
4. Apply the EF Core migrations to create/update the database. Exact command: Not found in repo.
5. Run: dotnet run --project SurveyBasket.Api
6. In development, open <https://localhost:7099/swagger/index.html> or use <http://localhost:5033>.

Key evidence: Program.cs, DependencyInjection.cs, appsettings.json, launchSettings.json, controllers, services, ApplicationDbContext, and EF migrations.

Rendering note: generated in this environment without reportlab/poppler, so image-based visual verification was not available.
